

- A DML statement is executed when you:
 - Add new rows to a table ----- Insert
 - Modify existing rows in a table
 - Remove existing rows from a table —— Delete/ Truncate (DDL)
- A transaction consists of a collection of DML statements that form a logical unit of work.

INSERT Statement Syntax

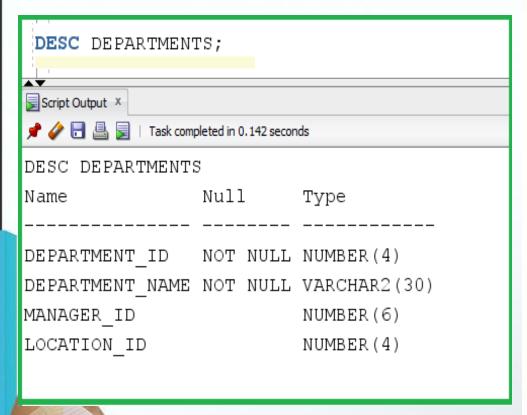

Add new rows to a table by using the INSERT statement:

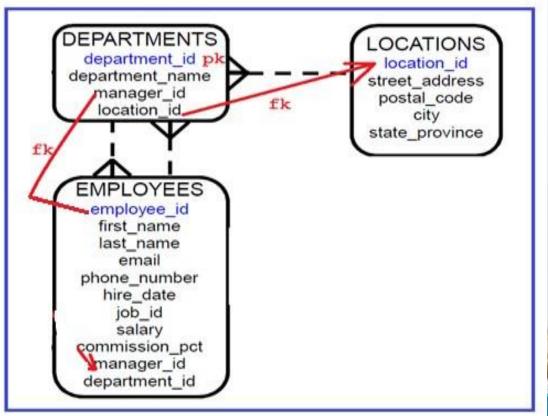

```
INSERT INTO table [(column [, column...])]
VALUES (value [, value...]);
```

With this syntax, only one row is inserted at a time.

1- You should know the table structure before you make any insert

2- you should know also the constraints on the table

Insert rules

- Insert a new row containing values for each column.
- List values in the default order of the columns in the table.
- Optionally, list the columns in the INSERT clause.
- Enclose character and date values within single quotation marks.

```
--list the columns in same table order, then put Related values (this is the Recommendation)
INSERT INTO DEPARTMENTS (DEPARTMENT_ID, DEPARTMENT_NAME, MANAGER_ID, LOCATION_ID)
                         (71, 'Development 1', 100, 1700);
VALUES
commit; -- use the commit command to save the changes
--you can make insert without puting the columns names, but the order in values should be same order of table
--this way of insert you need to put values for all the tables
INSERT INTO DEPARTMENTS
VALUES
         (72, 'Development 2', 100, 1700);
COMMIT;
--you can change the order as you like when put the columns names, but you should mapp the values same
INSERT INTO DEPARTMENTS (DEPARTMENT NAME, MANAGER ID, LOCATION ID, DEPARTMENT ID)
VALUES
                         ('Development 3', 100, 1700, 71);
```

Inserting Rows with Null Values

Implicit method: Omit the column from the column list.

Explicit method: Specify the NULL keyword in the VALUES clause.

```
INSERT INTO departments
VALUES (100, 'Finance', NULL, NULL);

1 rows inserted
```

Common errors that can occur during user input are checked in the following order:

- Mandatory value missing for a NOT NULL column
- Duplicate value violating any unique or primary key constraint
- Any value violating a CHECK constraint
- Referential integrity maintained for foreign key constraint
- Data type mismatches or values too wide to fit in column

Note: Use of the column list is recommended because it makes the INSERT statement more readable and reliable, or less prone to mistakes.

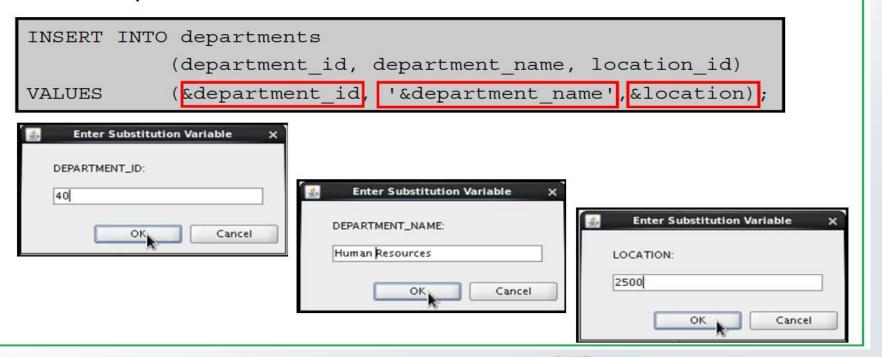

Inserting special values like sysdate, or some other functions

```
INSERT INTO EMPLOYEES (EMPLOYEE_ID,FIRST_NAME,LAST_NAME,EMAIL,HIRE_DATE ,JOB_ID)
VALUES (1,'khaled','khudari','khaled@hotmail.com',SYSDATE,'IT_PROG');
```

```
INSERT INTO EMPLOYEES (EMPLOYEE_ID,FIRST_NAME,LAST_NAME,EMAIL,HIRE_DATE ,JOB_ID)
VALUES (2,'Samer','ali','samer@hotmail.com',to_date('20-07-2015','dd-mm-yyyy'),'IT_PROG');
```

Creating a Script

- Use the & substitution in a SQL statement to prompt for values.
- & is a placeholder for the variable value.

Copying Rows from Another Table

Write your INSERT statement with a subquery:

```
INSERT INTO XX_EMP(EMPNO, FNAME, SALARY)
SELECT EMPLOYEE_ID, FIRST_NAME, SALARY
FROM
EMPLOYEES;
```

- Do not use the VALUES clause.
- Match the number of columns in the INSERT clause to those in the subquery.
- Inserts all the rows returned by the subquery in the table

UPDATE Statement Syntax

 Modify existing values in a table with the UPDATE statement:

```
UPDATE      table
SET      column = value [, column = value, ...]
[WHERE      condition];
```

Update more than one row at a time (if required).

Note: In general, use the primary key column in the WHERE clause to identify a single row for update. Using other columns can unexpectedly cause several rows to be updated. For example, identifying a single row in the EMPLOYEES table by name is dangerous, because more than one employee may have the same name.

you guarantee one row update

UPDATE EMPLOYEES

SET SALARY =24100

WHERE EMPLOYEE ID=100;

COMMIT;

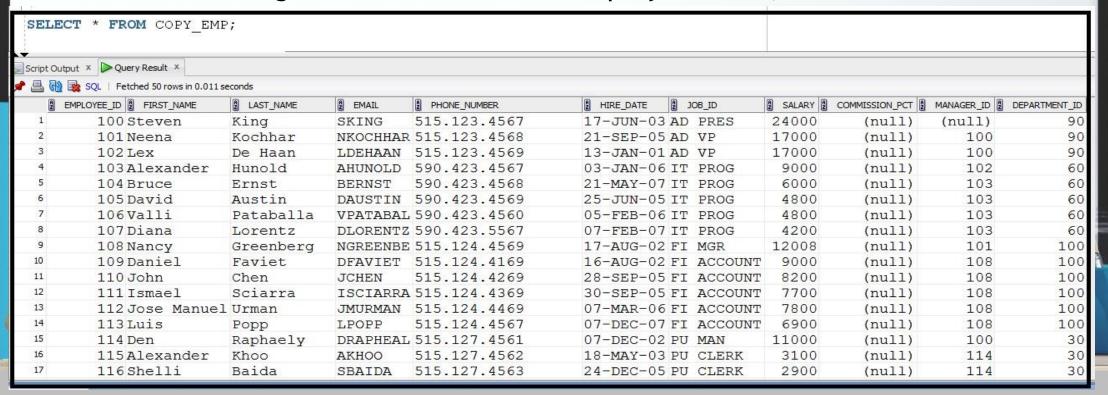

could be more than one employee with name='Steven > \

```
UPDATE EMPLOYEES
SET SALARY =24100
WHERE FIRST_NAME='Steven';
COMMIT;
```

 In order to do more practices lets create table called copy_emp And this table will be a copy from employees table To do this, we will execute the following SQL:

```
CREATE TABLE COPY_EMP
AS SELECT * FROM EMPLOYEES;
```

 This will create table exactly like employees, but without creating the constraints like employee table,

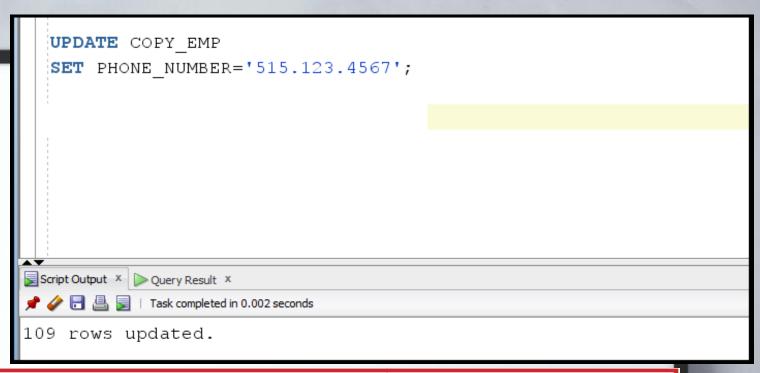

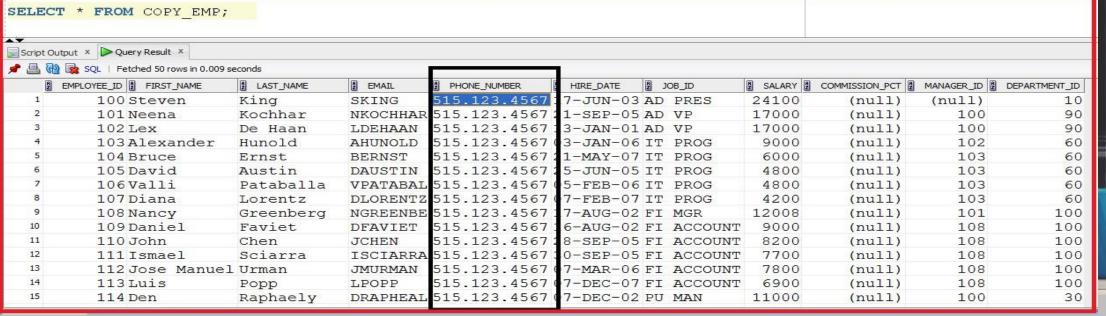

Updating more than one column in the same time

Usecomma (,) followed by column name

```
you can update more than one column in the same time
 UPDATE COPY EMP
 SET SALARY =24100, DEPARTMENT ID=10
 WHERE EMPLOYEE ID=100;
 COMMIT
 SELECT * FROM COPY EMP
 WHERE EMPLOYEE ID=100;
Script Output × Query Result ×
🕨 📇 祸 🗽 SQL | All Rows Fetched: 1 in 0.001 seconds
   2 EMPLOYEE_ID 2 FIRST_NAME 2 LAST_NAME 2 EMAIL 2 PHONE_NUMBER 2 HIRE_DATE 2 JOB_ID
                                                                         SALARY COMMISSION_PCT MANAGER_ID DEPARTMENT_ID
         100 Steven King SKING 515.123.4567 17-JUN-03 AD PRES 24100
                                                                                       (null)
                                                                                                 (null)
```

IF there is no where condition then the statement will update all the tables

You can set the column to null in the update statement

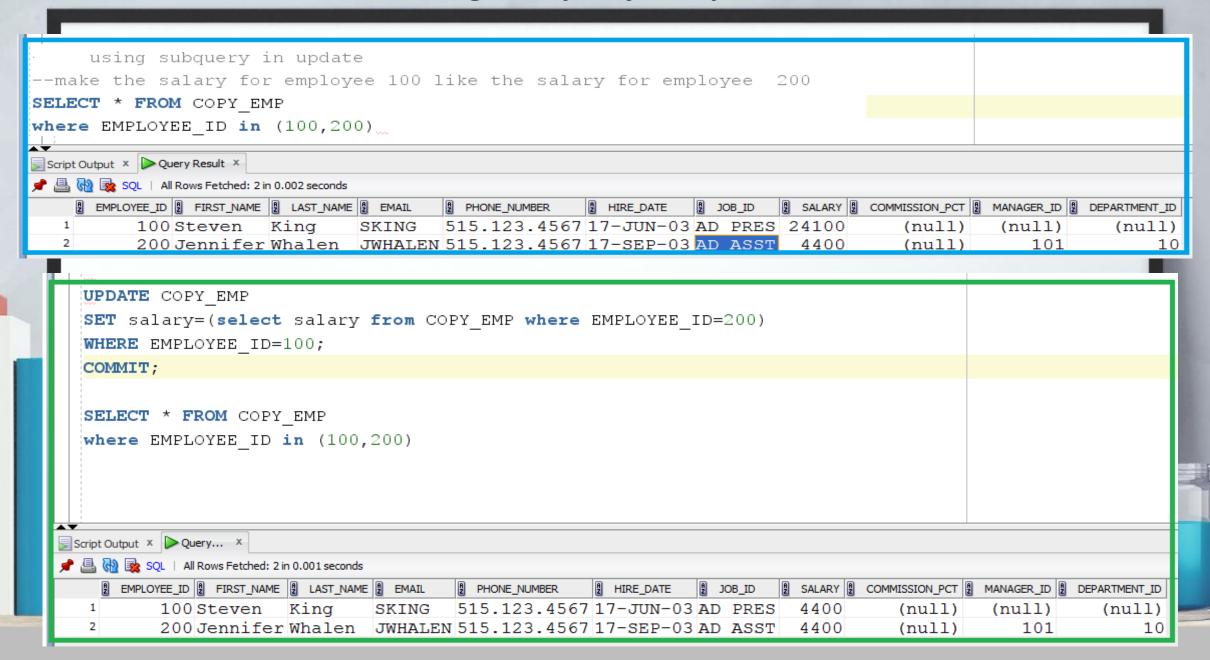

```
UPDATE COPY_EMP
SET DEPARTMENT_ID=NULL
WHERE EMPLOYEE_ID=100;

COMMIT;

SELECT * FROM COPY_EMP
WHERE EMPLOYEE_ID=100;
```

But there is nothing in selectcolumn =null In select we use column is null/ column is not null

Using Subquery in Update

Using Subquery in Update

make the salary and department id for employee 105 like the salary and department id for employee 108

```
UPDATE COPY_EMP
SET (salary,department_id) =(select salary, department_id from COPY_EMP where EMPLOYEE_ID=108)
WHERE EMPLOYEE_ID=105;

--method 2
UPDATE COPY_EMP
SET SALARY =(SELECT SALARY FROM COPY_EMP WHERE EMPLOYEE_ID=108),
department_id =(select department_id from COPY_EMP where EMPLOYEE_ID=108)
WHERE EMPLOYEE_ID=105;
```

Update based on another table

Make all the salaries in table copy_emp like the salaries in table employees

In this case the additional rows in table copy_emp that doesn't meet the conditions will be updated by null values.

When there is no where in the SQL statement this mean all rows will be updated

```
UPDATE COPY_EMP C
SET SALARY = (SELECT SALARY FROM EMPLOYEES E WHERE E.EMPLOYEE_ID=C.EMPLOYEE_ID );
```

```
UPDATE COPY_EMP C
SET SALARY = (SELECT SALARY FROM EMPLOYEES E WHERE E.EMPLOYEE_ID=C.EMPLOYEE_ID )
where exists(select 1 from EMPLOYEES emp where emp.employee_id=c.EMPLOYEE_ID)
```

DELETE Statement

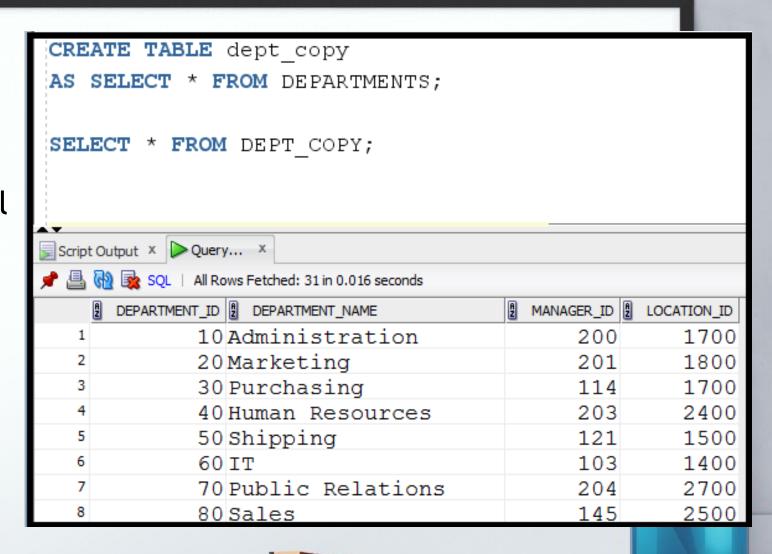

You can remove existing rows from a table by using the DELETE statement:

```
DELETE [FROM] table [WHERE condition];
```

Note: If no rows are deleted, the message "0 rows deleted" is returned (on the Script Output tab in SQL Developer).

We will create table dept_copy in order to do some practices

Note: dept_copy table will have no constraints (PK,FK,..)
Because create table based on select doesn't copy any constraint like PK,FK But it make copy for not null constraints

```
DELETE from DEPT_COPY
WHERE DEPARTMENT_ID=10;
COMMIT;
```

The will return 1 row deleted

```
DELETE DEPT_COPY
WHERE DEPARTMENT_ID=10;
COMMIT;
```

this will return 0 rows deleted, you already deleted in the previous SQL

note: the keyword FROM is optional

You can rollback this update, but before doing commit, If you do commit, then you can not do rollback

```
if there is no where condition then all rows in the table will be deleted

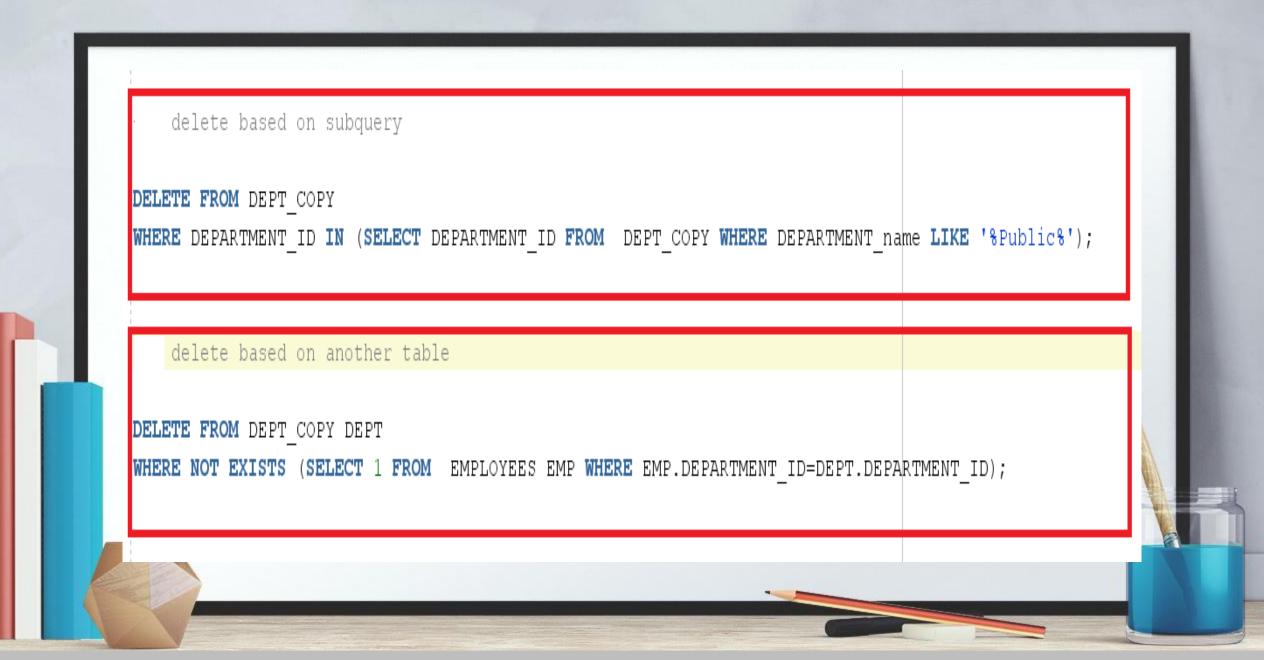

DELETE DEPT_COPY;

Script Output * Query Result *

Query Result *

Task completed in 0.001 seconds

30 rows deleted.
```

TRUNCATE Statement

- Removes all rows from a table, leaving the table empty and the table structure intact
- Is a data definition language (DDL) statement rather than a DML statement; cannot easily be undone
- Syntax:

TRUNCATE TABLE table_name;

Example:

TRUNCATE TABLE copy emp;

A more efficient method of emptying a table is by using the TRUNCATE statement. You can use the TRUNCATE statement to quickly remove all rows from a table or cluster. Removing rows with the TRUNCATE statement is faster than removing them with the DELETE statement for the following reasons:

- The TRUNCATE statement is a data definition language (DDL) statement and generates
 no rollback information.
- Truncating a table does not fire the delete triggers of the table.

If the table is the parent of a referential integrity constraint, you cannot truncate the table. You need to disable the constraint before issuing the TRUNCATE statement.

Delete	Truncate	
DML Statement	DDL Statement	
You can rollback	No rollback	
Fire the triggers	Not fire the triggers	
It could have where clause	No Where clause	
Delete does not recover space	recover space	
Delete from x;	truncate table x;	
).		

Database Transactions

A database transaction consists of one of the following:

- DML statements that constitute one consistent change to the data
- One DDL statement
- One data control language (DCL) statement

Example1: DML statements from one transaction

one Transaction

	emp		DML1 done by user HR
emp_id	name	sal	
102	khaled	500	
103	nader	700	update emp
			set sal=300
			where emp_id=102

	emp	
emp_id	name	sal
102	khaled	300
103	nader	700

emp_audit						
	DML 2 done by trigger					
emp_id	name	old	new	done_by	by_date	
102	khaled	500	300	HR		10-Jan-16

there is trigger insert into emp_audit after doing any update

Example2: DDL statement (one transaction)
Create table emp_copy as select * from employees
Example3: DCL statement (one transaction) Grant select
on hr.employees to scott

Database Transactions: Start and End

- Begin when the first DML SQL statement is executed.
- End with one of the following events:
 - A COMMIT or ROLLBACK statement is issued.
 - A DDL or DCL statement executes (automatic commit).
 - The user exits SQL Developer or SQL*Plus.
 - The system crashes.

Advantages of COMMIT and ROLLBACK Statements

With COMMIT and ROLLBACK statements, you can:

- Ensure data consistency
- Preview data changes before making changes permanent
- Group logically related operations

Explicit Transaction Control Statements

You can control the logic of transactions by using the COMMIT, SAVEPOINT, and ROLLBACK statements.

Statement	Description
COMMIT	COMMIT ends the current transaction by making all pending data changes permanent.
SAVEPOINT name	SAVEPOINT <i>name</i> marks a savepoint within the current transaction.
ROLLBACK	ROLLBACK ends the current transaction by discarding all pending data changes.
ROLLBACK TO SAVEPOINT name	ROLLBACK TO SAVEPOINT rolls back the current transaction to the specified savepoint, thereby discarding any changes and/or savepoints that were created after the savepoint to which you are rolling back. If you omit the TO SAVEPOINT clause, the ROLLBACK statement rolls back the entire transaction. Because savepoints are logical, there is no way to list the savepoints that you have created.

Implicit Transaction Processing

- An automatic commit occurs in the following circumstances:
 - A DDL statement issued
 - A DCL statement issued
 - Normal exit from SQL Developer or SQL*Plus, without explicitly issuing COMMIT or ROLLBACK statements
- An automatic rollback occurs when there is an abnormal termination of SQL Developer or SQL*Plus or a system failure.

Note: In SQL*Plus, the AUTOCOMMIT command can be toggled ON or OFF. If set to ON, each individual DML statement is committed as soon as it is executed. You cannot roll back the changes. If set to OFF, the COMMIT statement can still be issued explicitly. Also, the COMMIT statement is issued when a DDL statement is issued or when you exit SQL*Plus. The SET AUTOCOMMIT ON/OFF command is skipped in SQL Developer. DML is committed on a normal exit from SQL Developer only if you have the Autocommit preference enabled.

System Failures

When a transaction is interrupted by a system failure, the entire transaction is automatically rolled back. This prevents the error from causing unwanted changes to the data and returns the tables to the state at the time of the last commit. In this way, the Oracle server protects the integrity of the tables.

In SQL Developer, a normal exit from the session is accomplished by selecting Exit from the File menu. In SQL*Plus, a normal exit is accomplished by entering the EXIT command at the prompt. Closing the window is interpreted as an abnormal exit.

State of the Data Before COMMIT or ROLLBACK

- The previous state of the data can be recovered.
- The current session can review the results of the DML operations by using the SELECT statement.
- Other sessions cannot view the results of the DML statements issued by the current session.
- The affected rows are locked; other session cannot change the data in the affected rows.

State of the Data After COMMIT

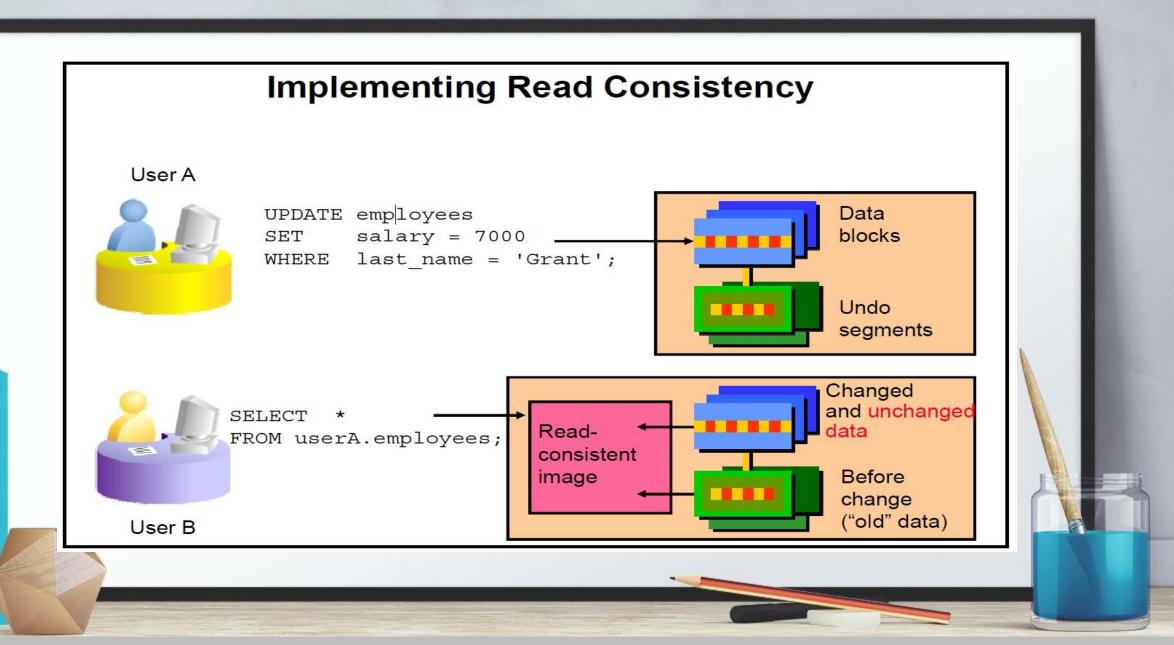

- Data changes are saved in the database.
- The previous state of the data is overwritten.
- All sessions can view the results.
- Locks on the affected rows are released; those rows are available for other sessions to manipulate.
- All savepoints are erased.

Read Consistency

- Read consistency guarantees a consistent view of the data at all times.
- Changes made by one user do not conflict with the changes made by another user.
- Read consistency ensures that, on the same data:
 - Readers do not wait for writers
 - Writers do not wait for readers
 - Writers wait for writers

The purpose of read consistency is to ensure that each user sees data as it existed at the last commit, before a DML operation started.

Note: The same user can log in to different sessions. Each session maintains read consistency in the manner described above, even if they are the same users.

Read consistency is an automatic implementation. It keeps a partial copy of the database in the undo segments. The read-consistent image is constructed from the committed data in the table and the old data that is being changed and is not yet committed from the undo segment.

When an insert, update, or delete operation is made on the database, the Oracle server takes a copy of the data before it is changed and writes it to an *undo segment*.

All readers, except the one who issued the change, see the database as it existed before the changes started; they view the undo segment's "snapshot" of the data.

Before the changes are committed to the database, only the user who is modifying the data sees the database with the alterations. Everyone else sees the snapshot in the undo segment. This guarantees that readers of the data read consistent data that is not currently undergoing change.

When a DML statement is committed, the change made to the database becomes visible to anyone issuing a SELECT statement *after* the commit is done. The space occupied by the *old* data in the undo segment file is freed for reuse.

If the transaction is rolled back, the changes are undone:

- The original, older version of the data in the undo segment is written back to the table.
- All users see the database as it existed before the transaction began.

FOR UPDATE Clause in a SELECT Statement

• Locks the rows in the EMPLOYEES table where job_id is SA_REP.

```
SELECT employee_id, salary, commission_pct, job_id
FROM employees
WHERE job_id = 'SA_REP'
FOR UPDATE
ORDER BY employee_id;
```

- Lock is released only when you issue a ROLLBACK or a COMMIT.
- If the SELECT statement attempts to lock a row that is locked by another user, the database waits until the row is available, and then returns the results of the SELECT statement.

When you issue a SELECT...FOR UPDATE statement, the relational database management system (RDBMS) automatically obtains exclusive row-level locks on all the rows identified by the SELECT statement, thereby holding the records "for your changes only." No one else will be able to change any of these records until you perform a ROLLBACK or a COMMIT.
